ABSTRACT

Background: Patientsafety is a global medical concern with remarkable influence on the health of patients. Studies have suggested that treatment-related damages occur in approximately 10% of patients at variable degrees, and more than a quarter of these damages are associated with medication errors. Medication errors could be diminished during patient hospitalization and transferring integrated medication reconciliation. This study aimed to evaluate the determinants of completing integrated medication reconciliation forms based on the theory of diffusion of innovations among the nurses of Ziaei Hospital of Ardakan City and Imam Jafar Sadegh Hospital of Meybod City, Yazd.

Materials and Methods: In this study, required data were collected from the nurses engaged in the admission centers of the selected hospitals using researcher-made questionnaires. Data analysis was performed in SPSS v. 19 using Spearman’s correlation-coefficient and Mann-Whitney U test.

Results: Findings of this study regarding different structures of integrated medication reconciliation forms were as follows: relative advantage (86.5 of the maximum score), perceived compatibility (40.75), perceived complexity (44.3), visibility (83.6), and testability (79.8). Moreover, significant correlations were observed between the structures of comparative advantage, perceived compatibility, testability, and visibility.

Conclusion: According to the results of this study, promoting the knowledge and professional attitude of nurses could increase their compatibility regarding the implementation of integrated medication reconciliation. In addition, elaboration on the proper principles of the completion of this form could reduce the mean score of the perceived complexity structure.
Introduction

Patient safety is a global medical concern in all areas of healthcare services in developed and developing countries. Statistically, it has been found that treatment-borne damages occur in approximately 10% of all hospitalized patients at variable degrees [1].

Based on studies conducted in Australia, 16.6% of hospitalized patients experience adverse events, which may lead to temporary disabilities (77%), permanent disabilities (15%), and death (5%) [2].

Recent reports have confirmed that medication errors account for more than a quarter of problems affecting patients during hospitalization and treatment [3, 4]. Medication errors mostly occur during the processes of preparation, prescription, distribution, and monitoring of therapeutic drugs. Time of admission has been recently proposed as a significant factor in the occurrence of treatment-related complications. More than 50% of patients had been subjected to medication errors at the time of admission due to errors in their medical history [5].

Medication errors can lead to several problems, including high hospitalization costs, increased mortality rate, and lack of patients’ trust and satisfaction with hospital services [6]. In Iran, the Ministry of Health and Education allocates billions of dollars every year to compensate for the cost of medication and admission errors [7].

However, many medication errors are preventable and can be corrected with efficient management. Based on a study, 48% of these errors are preventable [1]. According to the results of another study, two-thirds of patients’ complications upon admission were reported to be preventable with efficient management [8]. Incompatibility in prescribed drugs after discharge plays a critical role in the occurrence of adverse medical events. Discharged patients are at a higher risk of complications caused by medication incompatibility as they return to normal social life [9, 10]. In this regard, the findings of Forrestor indicate that 23% of the patients discharged from a teaching hospital in Canada experienced unwanted side effects, 72% of which were associated with drug administration [11].

Medication reconciliation is an effective strategy to reduce medication errors and several studies have proved its effectiveness [12]. For instance, the results of a report confirmed that integrated medication reconciliation could reduce medical errors by 70% within 7 months [13]. Medication reconciliation is mainly based on providing a complete medical history, which differs from the routine medical record of the patient [1]. The required medical history is provided through a systematic process of interviewing the patient and referring to credible sources (e.g., pharmacies and physicians) [14]. However, since the patient’s interview may be time-consuming, healthcare providers tend to neglect this process, which exposes patients to a higher risk of unexpected medication and treatment-related errors [15]. Furthermore, integrated medication reconciliation is widely used for patients who are unfamiliar with prescription medications.

Diffusion of innovations is a theory of the main principles used to facilitate the adoption of healthcare providers with a specific procedure. The proper implementation of this theory requires a suitable setting and the aspect of innovation highlights the ideas, issues, and functions that are considered unprecedented by another individual. In this context, the term “unprecedented” refers to the situation in which a potential recipient has had no previous contact with the other applications of a certain new product or idea [16].

In applying the diffusion of innovations theory, health authorities are faced with unestablished interventions and their impact on a certain process [17]. For a new approach to become established and widely practiced, three main components are required: the new idea must be accepted by influential people, the new idea must be of great quality or with notable characteristics to encourage people to follow the idea, and the new idea must have remarkable environmental and social impacts [18].

In a study, Forster et al. measured the acceptance rate of preventive pharmaceutical procedures in a medical high school in 2002. According to the findings, the two structures of relative advantage and perceived compatibility were most effective in the adoption of new processes [19].

In this regard, another research was conducted by McGa et al. to evaluate the role of a multi-team approach in patient transfer in 2007, emphasizing the safety of patients. According to the findings, more than 90% of discharged patients had at least one potential exposure to medication side effects. In their study, adequate training of nurses and improvement of nursing skills in medication assessment reduced the risk of mortality by at least 78%. Furthermore, less than 28% of the patients required follow-up and revisits which ultimately reduced treatment costs [20].
Considering the importance of medication reconciliation and the creation of an appropriate framework for the proper acceptance of this process, the researchers tried to investigate the determinants of using medication reconciliation in nurses based on diffusion of innovation theory.

**Methods**

This cross-sectional study was conducted on 91 nurses engaged in intensive care units, internal medicine departments, surgery wards, cardiac care units, gynecology, and pediatric wards in two general hospitals in Ardakan and Meybod Cities of Yazd Province, in May 2016. The participants completed a researcher-made questionnaire designed based on the diffusion of innovations theory. The validity of the questionnaire was reviewed by a panel of experts and its content validity ratio and content validity index were examined and approved. To remove any ambiguity in understanding each item, the questionnaire was sent to 10 nurses and their comments were taken. The reliability of the questionnaire was also evaluated by conducting a pilot study on 15 nurses who were later excluded from the study. The final questionnaire included the following subscales:

1. Relative advantage: This construct contains 6 items and the acquired score ranges from 6 to 35. In this construct, the positive results of the reconciliation form are questioned. Its reliability is 0.87 calculated by the Cronbach α coefficient.

2. Perceived compatibility: This construct includes 4 items to measure the compatibility of integrated medication with professional requirements (α=0.59).

3. Visibility: It includes two items scoring based on a 5-point Likert scale from completely correct to completely wrong. The possible scores ranged from 2-10 (α=0.74).

4. Testability: This construct is measured with 2 items based on a 5-point Likert scale. The possible score for the construct ranged from 2-10 (α=0.62).

5. Perceived complexity: In this structure, 4 items are scored inversely. If the completion or learning of the form is considered hard, it will gain lower scores. The acquired score ranged from 4-20 (α=0.56). Subjective norms (with six items) (α=0.75) and intention (with three items) (α=0.65) are the other constructs.

The collected data were entered into SPSS v.13. One-sample Kolmogorov-Smirnov test showed that the data were non-normally distributed. Thus, the Spearman rank correlation coefficient was used to determine the correlation between variables and the Mann-Whitney U test was used to compare the groups (significance level at <0.05).

**Results**

In total, 91 nurses were enrolled in this study, selected via census sampling. They were assured of the confidentiality of the information, and then the questionnaires were provided to them to complete.

The participants’ Mean±SD of age was 34.36±7.25 years. In terms of educational status, 10 participants had a diploma in paramedical sciences and 57 nurses a BA in nursing. Their Mean±SD clinical experience was 10±8.15 years (range: 1-26 years). Besides, 30 participants were male (33.3%) and 60 were female (65.9%).

According to Table 1, 40% of the nurses found it difficult to complete integrated medication reconciliation forms, and 80% did not consider this healthcare strategy to be in line with clinical professional values. Moreover, 78% of the participants were concerned that the implementation of the integrated medication program might interfere with their working time frame.

Concerning the structure of relative advantage, the majority of the nurses agreed with the benefits of the integrated medication reconciliation. As such, 82% of nurses believed that the use of this healthcare strategy contributed to effective patient management.

As revealed in Table 2, two structures of perceived complexity (44.3%) and relative advantage (40.75%) received the lowest scores obtained by the participants, while the structures, intention (91.83%) and relative advantage (86.5%) had the highest scores obtained by the participants.

The mean score of relative advantage was higher among male participants, and there was a significant difference in this regard (P=0.034). Furthermore, the mean scores of the structures, perceived complexity (P=0.001), and intention (P=0.013) were higher among male participants, and significant differences were observed in this regard.

Table 3 indicates a direct correlation between the structures of perceived relative advantage and intention to
complete the integrated medication reconciliation forms. Therefore, a higher mean score of relative advantage resulted in the increased mean score of the intention structure; however, this correlation was not significant. Moreover, the correlations between the constructs of testability and visibility were not statistically significant.

**Discussion**

In the present study, the mean scores of different structures of diffusion of innovations theory were evaluated among the nursing staff of two public hospitals. According to the findings, the highest scores belonged to the structures of perceived relative advantage, testability, and visibility, while the lowest scores belonged to the structures of perceived compatibility and complexity. Therefore, the majority of nurses believed that the completion of integrated medication reconciliation forms is difficult or interferes with their professional values and working timeframe.

As shown in Table 1, 40% of the nurses found it difficult to complete the forms of integrated medication reconciliation; 80% did not believe this strategy to be in line with professional values, and nearly 78% were concerned that this program might interfere with their working time frame. Furthermore, the results of the present study indicated that the structures of relative advantage, perceived compatibility, and perceived complexity of social networks were positively correlated with the tendency of nursing staff toward using these networks. In other studies, the lack of dissemination and acceptance of the innovation has been due to the complexity of health systems [21, 22].

| Learning to complete integrated medication reconciliation forms is difficult for nurses. | 9 (9.9) | 29 (31.9) | 30 (33) | 20 (22.0) | 3 (3.2) |
| The use of integrated medication reconciliation forms        | 10 (11) | 18 (19.8) | 36 (39.6) | 22 (24.2) | 5 (5.4) |
| It is quite easy to complete integrated medication reconciliation forms even for nurses who attempt to do it for the first time. | 5 (5.5) | 33 (36.3) | 29 (31.8) | 20 (22) | 4 (4.4) |
| It is my professional duty to implement integrated medication reconciliation. | 27 (29.7) | 40 (44) | 17 (18.7) | 4 (4.4) | 3 (3.2) |
| Nurses are concerned whether the use of integrated medication reconciliation interferes with their working time. | 1 (1.1) | 5 (5.5) | 14 (15.3) | 45 (49.5) | 26 (28.6) |
| Integrated medication reconciliation is in line with professional values. | 1 (1.1) | 3 (3.3) | 16 (17.5) | 41 (45.1) | 30 (33) |
| The implementation of integrated medication determines the list of required drugs for patients. | 41 (45.1) | 43 (47.3) | 4 (4.4) | 2 (2.2) | 1 (1.1) |
| The implementation of integrated medication reconciliation prevents the misuse or excessive consumption of previous drugs by the patient. | 42 (46.2) | 36 (39.6) | 8 (8.8) | 4 (4.3) | 1 (1.1) |
| The proper use of integrated medication reconciliation contributes to effective patient management. | 39 (42.8) | 40 (44) | 9 (9.9) | 2 (2.2) | 1 (1.1) |
The complexity of systems can be related to the structure, process, and patterns. For example, to change the method of drug delivery in a hospital, there needs to be a change in the real environment. In a system, individual factors, patterns of relationships, and beliefs should be considered. Overlooking these factors can cause more complexity of the system, as observed in the present study [21]. The findings of the current study confirmed the correlation between the tendency towards the application of the innovation theory and the use of social networks. With respect to the relative advantage construct, 82.2% of the nurses believed that the implementation of integrated medication reconciliation contributed to effective patient management. In this regard, a study was conducted by Abdullah Al-Mubariz Saud et al. [23] in which the rate of the internet acceptance was measured based on Roger’s diffusion of innovations theory, and recipients were categorized into innovators, early majority, late majority, delayed recipients, and survivors. According to the results of multiple regression analysis, the researchers concluded that the innovation structures, including relative advantage, perceived complexity, testability, perceived compatibility, and visibility were effective in the acceptance of the internet by the participants. Furthermore, they reported that the structure of relative advantage had the most significant effect on the rate of internet acceptance compared to the other aspects of innovation. In the present study, the relative advantage structure was positively correlated with the intention of nursing personnel to complete integrated medication reconciliation forms [24].

Compatibility is another key element of innovation diffusion, which can influence the reception and the use of innovation. In the current study, the majority of the nurses were concerned that the implementation of integrated medication reconciliation might interfere with their working time frame, suggesting that this healthcare strategy has not been considered by nursing personnel. Therefore, nurses should be assured that the implementation of this program helps with their professional values. This finding was consistent with the results obtained by Forster et al. that evaluated the attitude towards preventive procedures in a medical high school in 2002 [19]. According to their findings, the two structures of relative advantage and perceived compatibility were essentially

*p<0.1; **p<0.05
correlated with the tendency of healthcare staff towards the use of new pharmaceutical approaches [19].

Vedela et al. study results indicate that in individuals with a lower perception of the complexity of clinical systems, there is a direct correlation between comprehended simplicity and reduced perceived complexity [25]. Moreover, the perception of the functionality of the system is correlated with the relative advantage structure, and concerns regarding the patient-physician relationship are associated with the compatibility of the system. Accordingly, the higher perception of the functionality of the system is correlated with the structure of relative advantage [26].

The findings of the current study indicate a direct correlation between the structures of testability and visibility and the structure of tendency to complete the forms of integrated medication reconciliation among nurses. This finding was in line with the results obtained by Khalesi et al. assessing the users of hospital information systems [27]. Furthermore, the authors stated that visibility had a significant effect on the tendency of hospital staff towards the use of information systems. In this regard, the findings of Pankratz et al. revealed that in the proposed diffusion of innovations theory, innovation structures (visibility, perceived compatibility, professional relations, and internal and external environment) were significant predictors of the attitude of healthcare professionals towards the use of smartphones [28].

In other related studies, factors such as the reception of consumption management systems, human and ergonomics factors in the hospital, and different structures of innovation in rehabilitation management had significant associations with relative advantage, perceived compatibility, and perceived complexity. These findings are consistent with the results of the present study [29, 30].

Therefore, it is suggested that the modified version of the diffusion of innovations theory is adopted as a proper measure for clinical data collection to predict and comprehend the use of social networks.

Conclusion

The results of the current study indicated that acceptance of innovation in the completion of integrated medication reconciliation forms requires the increasing of nursing staff knowledge, as well as the reduction of the complexity of this strategy to help with the nursing profession. The researcher pointed out that the study lacked any impact on the performance of the personnel and their perception could affect the process of completing the questionnaire.

Ethical Considerations

Compliance with ethical guidelines

This study is a part of a protocol approved by the Ethics Committee of Shahid Sadoughi University of Medical Sciences, Yazd, Iran (Code: IR.SSU.PH.REC.1395.76).

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or non-profit sectors.

Authors' contributions

Conceptualization and Writing – Original Draft: Mojtaba Fattahi Ardakani; Methodology and Writing – Review & Editing: Sara Heydari sharifabad, Mojtaba Fattahi Ardakani; Investigation: all author; Funding Acquisition and Supervision: Sara Heydari sharifabad.

Conflict of interest

The authors declared no conflict of interest.

Acknowledgments

The authors appreciate the people who participated in this work, including the managers and nurses of Imam Jafar Sadegh Hospital of Meybod and Ziaee Hospital of Ardakan.
