ABSTRACT

COVID-19 patients with a history of cardiovascular diseases and elevated cardiac biomarkers are more susceptible to serious complications and have a poorer prognosis than other individuals. In the present case series, we reported a number of COVID-19 patients who experienced myocardial infarction (MI) at the Shahid Mostafa Khomeini Hospital of Ilam. By examining COVID-19 patients who had chest pain and electrocardiogram (ECG) abnormalities, we identified 10 patients (8 men and 2 women) who had experienced MI. All cases were over 60 years old. Of the patients, 3 cases (30%) died, and 7 cases (70%) recovered. Although MI is not common in COVID-19 patients, it is associated with high mortality. Preventive measures can be considered to avoid MI in these patients. It is recommended to screen for infectious diseases, including COVID-19, in individuals with cardiovascular problems.

Keywords: COVID-19, Myocardial infarction (MI), Polymerase chain reaction (PCR)

Introduction

CCOVID-19 primarily affects the respiratory system and causes respiratory disorders, reduced O₂ saturation, and respiratory distress in patients [1]. Patients with a history of underlying diseases (heart failure, infarction, hypertension, and heart valve replacement), as well as those with cardiac risk factors (elevated cardiac enzymes such as troponin, LDH, and CPK) and elevated levels of lipids, triglycerides, cholesterol, LDL, and reduced HDL, are more vulnerable to the disease's complications and have a poorer prognosis [2].

Ruan et al. showed that COVID-19-related mortality was significantly associated with cardiovascular failure [3]. Another study stated that underlying diseases, such as hypertension, can increase the mortality rate in COVID-19 patients by up to 2.5 times [4]. Although the clinical manifestations of COVID-19 in patients with heart failure are unknown, clinical evidence from patients with end-stage heart failure indicates that the virus is associated with direct cardiac damage [5-7].

COVID-19 is also associated with patients' demographic features. Most deaths occur in older men with a mean age of 75 years who have a history of underlying conditions, such as diabetes, hypertension, heart disease, chronic respiratory disease, cancer, or prior surgeries. COVID-19 also triggers cardiovascular complications by causing arterial and venous thrombosis. The mechanisms of thrombosis in this disease include inducing inflammation, platelet activation, as well as vascular dysfunction and occlusion. Accordingly, antithrombotic drugs constitute a part of the treatments provided to COVID-19 patients [8].

The mechanisms proposed for COVID-19-related cardiovascular diseases suggest that cardiac problems may result from an imbalance between metabolic demand and cardiac reserve. This imbalance, in association with inflammatory conditions and myocardial damage, can increase the risk of acute coronary artery syndrome, heart failure, arrhythmias, and myocardial infarction (MI) [9].

One of the laboratory parameters that predicts cardiac ischemia and mortality in COVID-19 is cardiac troponin I. It should be noted that elevated cardiac troponin I in patients with COVID-19 is merely an indicator of cardiac damage and causes secondary severe hypoxemia [10].

Although most studies regard cardiac damage and heart failure as risk factors for morbidity and mortality, one

study declared that the virus itself was the direct cause of death in a patient who had no history of cardiovascular disease and heart failure; nevertheless, the exact mechanisms of heart failure remain to be identified [11].

MI is the most dreadful complication of heart diseases and is responsible for a large number of patients' deaths. The aim of this report was to describe MI in a series of COVID-19 patients referred to the Shahid Mostafa Khomeini hospital in Ilam from March 2020 to January 2021.

Case Presentations

The selection of cases and samples included patients who had a confirmed diagnosis of MI based on blood tests (troponin) or evident electrocardiogram (ECG) changes, and these individuals also had a positive polymerase chain reaction (PCR) test. The diagnostic criteria for confirming MI included positive troponin (NSTEMI) and ST-segment elevation on ECG (STEMI). The data source was cross-sectional, covering the period from March 2020 to March 2021. Out of ten COVID-19 patients, 8(80%) were elderly men, and 2(20%) were elderly women, indicating a male/female ratio of 4:1. All the patients were over 60 years old (i.e. elderly). Of these, six (60%) were classified as young elderly (aged 60 to 74 years), one (10%) as middle-aged elderly (aged 75 to 84 years), and three (30%) as very old (over 85 years).

Ten cases of MI were identified by examining COVID-19 patients who complained of chest pain and had ECG abnormalities. Table 1 reports the echocardiographic results of the patients and discusses parameters such as ejection fraction, size, mitral regurgitation, tricuspid regurgitation, and pulmonary arterial pressures.

Case 1: A 92-year-old man was referred to the emergency department with weakness and fatigue. After a positive troponin test, cardiology counseling was requested. Due to the presence of a pacemaker and the poor performance of the instrument, an ECG was not obtained.

Case 2: An 82-year-old man with acute coronary syndrome/possible pulmonary thromboembolism (ACS/RO PTE) was referred to the emergency department. The ECG showed abnormal patterns (Table 1). Troponin and C-reactive protein (CRP) were positive, and the erythrocyte sedimentation rate (ESR) was elevated. A high-resolution computed tomography (HRCT) scan was performed by a cardiologist, and a PCR test returned a positive COVID-19 result.

Table 1. Echocardiography findings of COVID-19 patients

Case	Ejection Fraction	Size	Mitral Regurgitation	Tricuspid Regurgitation	Pulmonary Arterial Pressure (mm Hg)
1	Severely reduced	Mild elevation	Mild	Mild	30
2	Preserved	Normal	Mild	Mild	25
3	Severely reduced	Mild elevation	Mild	Mild	25
4	Severely reduced	Normal	Mild	Mild	25
5	Severely reduced	Normal	Mild	Mild	30
6	Moderately reduced	Normal	Normal	Mild	30
7	Moderately reduced	Normal	Mild	Mild	30
8	Preserved	Normal	Mild	Mild	30
9	Preserved	Normal	Mild	Mild	45
10	Severely reduced	Normal	Mild	Mild	35

Case 3: A 90-year-old man with COVID-19 was admitted to the infectious diseases ward. Based on ECG alterations (Table 1) and the results of laboratory tests (positive troponin, high ESR, and positive CRP), a cardiology consultation was requested.

Case 4: A 73-year-old woman was admitted to the infectious diseases ward with a diagnosis of COVID-19. After examining ECG patterns (Table 1) and considering the results of relevant tests (positive troponin, high ESR, and positive CRP), a cardiology consultation was requested.

Case 5: A 67-year-old woman with a diagnosis of COVID-19 was admitted to the infectious diseases ward. Following an assessment of the ECG changes (Table 1) and based on the results of laboratory tests (positive troponin, high ESR, and positive CRP), a cardiology consultation was requested, which resulted in a diagnosis of non-ST-segment elevation MI.

Case 6: A 91-year-old male with a diagnosis of COVID-19 was admitted to the infectious diseases ward. According to ECG findings, positive troponin and CRP tests, and elevated ESR, a cardiology consultation was requested, resulting in the diagnosis of MI.

Case 7: A 73-year-old man was admitted to the infectious diseases ward with a diagnosis of COVID-19. A cardiology consultation was requested because of ECG abnormalities (Table 1), positive troponin and CRP tests,

and elevated ESR. The patient ultimately died from complications of the disease.

Case 8: A 63-year-old male with a diagnosis of COVID-19 was admitted to the internal medicine ward. Based on ECG abnormalities (Table 1) and the results of laboratory tests (positive troponin, high ESR, and positive CRP), a cardiology consultation was requested. He was diagnosed with non-ST-segment elevation MI.

Case 9: A 67-year-old man with a diagnosis of COVID-19 was admitted to the infectious diseases ward. According to ECG findings (Table 1), positive troponin and CRP tests, and elevated ESR, a cardiology consultation was requested.

Case 10: A 60-year-old female was admitted to the infectious diseases ward with a diagnosis of COVID-19. Based on ECG findings, positive troponin and CRP tests, and elevated ESR, a cardiology consultation was requested.

ECG images are shown separately in [Figure 1](#).

Discussion

The present study examined MI in COVID-19 patients as a case series. According to a study by Shi et al., elderly cardiac patients with myocardial damage and decreased ejection fraction (EF) who contracted COVID-19 experienced more pronounced cardiac injuries and significantly higher mortality [12]. In a cohort study involving

a) Normal sinus rhythm/ normal axis / hyper acute T-tall wave V1-V4 / ST inversion V5-V6 / normal QT

b) Normal sinus rhythm/ left axis deviation/ left anterior fascicular block/ ST depression, inferior V4-V6/ normal QT

c) Normal sinus rhythm/ normal axis / normal T wave / normal QT

d) Sinus tachycardia/HR=110/ normal axis / LBBB/ normal QT.

e) Sinus rhythm/ first-degree AV block / abnormal axis/ ST depression V4-V6

f) Normal sinus rhythm/ left axis deviation/ left anterior fascicular block/ no ST-T changes / normal QT

g) Normal sinus rhythm/ normal axis/ ST elevation V1-V6/ normal QT

h) Normal sinus rhythm/ normal axis/ no ST and T changes/ normal QT

i) Sinus tachycardia/HR=120/ normal axis / T inversion V1-V4/ normal QT

j) Normal sinus rhythm/ normal axis / T inversion V2-V6 / normal QT.

Figure 1. ECG of research samples

416 COVID-19 patients, cardiac damage was reported in 19.7% of patients at admission and was identified as an independent risk factor for in-hospital mortality [12]. According to the results of the present study, 3 out of 10 patients (30%) died, while 7 patients (70%) recovered.

The mortality rate was higher among men than women. The mortality and severity of COVID-19 and SARS have been associated with factors, such as age and the presence of comorbidities. Although age was comparable between men and women, men with COVID-19 seem to experience a more severe disease. Overall, the number of men dying from COVID-19 was 2.4 times higher than that of women. While the prevalence of COVID-19 is similar between men and women, men seem to have a poorer prognosis and higher mortality rates independent of their age [13].

Timely diagnosis of MI in COVID-19 patients can help reduce mortality. Therefore, it is essential to identify suspected COVID-19 patients through regular assessment of ECG patterns and serum troponin levels.

New clinical experiences

COVID-19 is a severe inflammatory disease with a relatively high mortality rate. The disease can provoke MI; thus, monitoring patients for this condition can help reduce the mortality and morbidity associated with COVID-19. Due to the complex nature and unknown aspects of the disease, it is important to identify the mechanisms

of cardiac and coronary artery involvement. Due to the overlap between the cardiac and pulmonary complications of COVID-19, and because cardiac events may even be asymptomatic, screening cardiac function in all patients and providing timely treatments may significantly reduce mortality in these patients. It is noteworthy that some patients may have no symptoms of myocardial ischemia, and MI may present as the first sign in these patients. Due to the progressive nature of MI in COVID-19 patients, there is a need for early screening and immediate interventions.

Conclusion

Although MI is not common in COVID-19 patients, it has a high mortality rate and should be promptly managed with preventive measures.

Limitations

The small sample size was one of the limitations of the present study.

Recommendations

It is recommended that patients with cardiac conditions be screened for viral infections, especially COVID-19.

Ethical Considerations

Compliance with ethical guidelines

This study was approved by the Deputy of Research and Technology of [Ilam University of Medical Sciences](#), Ilam, Iran (Code: IR.MEDILAM.REC.1399.264). All participants provided written informed consent.
